The `try` block contains the code that could potentially raise an exception. If an exception is raised in the `try` block, the execution immediately moves to the `except` block that handles that specific exception.

The `requests.exceptions.RequestException` except block will handle any network errors that might occur during the API call or while downloading the image.

The `openai.api_errors.APIError` except block will handle any errors returned by the OpenAI API, such as incorrect parameters or exceeding rate limits.

Finally, the general `Exception` except block will catch any other exceptions that the specific catch blocks did not catch. This is a good practice to ensure that your program can recover from any unexpected exceptions.

Fill in the blanks:

In Python, a try block contains the code that could potentially raise an exception. If an exception is raised in this block, the execution immediately moves to the except block that handles that specific exception.

In Python, we use `try` and `except` blocks to catch and handle exceptions. The try block contains the code that might raise an exception. If an exception does occur, the rest of the try block is skipped and execution moves to the except block, which contains code that handles the exception.

Check It!
