exercise3.py ×

```
class Parent1:
  def identify(self):
    return "This method is called from Parent1"

class Parent2:
  def identify(self):
    return "This method is called from Parent2"

# declare child class here
class Child(Parent2, Parent1):
  def identify(self):
    return "This method is called from Child"

  def identify2(self):
    return super().identify()

child_object = Child()
print(child_object.identify())
print(child_object.identify2())
```

Collapse **Inheritance -> Coding Exercises - Inheritance**

Inheritance Exercise 3

Exercise 3

Create the class `Child` such that the following criteria are met:

- `Child` is a subclass of `Parent1` and `Parent2`
- Override `identify` so that it returns "This method is called from Child"
- Create the method `identify2` that invokes the `identify` method from `Parent2`. This **must** be done using the `super()` keyword.

Expected Output

Assume that `child_object` is an instance of the `Child` class. Then the following would be true:

- `child_object.identify()` would return `This method is called from Child`
- `child_object.identify2()` would return `This method is called from Parent2`

TRY IT

```
This method is called from
Child
This method is called from
Parent2
```

Submit your work when ready

Here is one possible solution:

```
class Parent1:
  def identify(self):
    return "This method is called fr

class Parent2:
  def identify(self):
    return "This method is called fr

# declare child class here
class Child(Parent2, Parent1):
  def identify(self):
    return "This method is called fr

  def identify2(self):
    return super().identify()
```

Check It!
