Yes

Deadline: You must submit this week's assignments by **November 15, 2015, 11:59 PM PT**.

Welcome! This week we will focus on models that divide data into two groups - Binary Classification. You will get a deep understanding of the quantitative metrics by which binary classification models are evaluated, and how the best model for a certain purpose is generally chosen. You will start to appreciate the different business situations that call for optimizing which classification metrics.

The Credit Card Business Case Study (Final Course Project) gives you an opportunity to experiment with combining relevant input variables into a credit card default risk score in various ways. You will then rank-order historical outcomes based on their scoring method, and optimize their method so as to maximize two different but equally critical binary classification metrics – the area under the ROC curve (AUC), and the model's cost per event.
