

The N Keyword Argument

```
prompts = "Write a tagline for an ice cream shop"
response = openai.Completion.create(model="text-davinci-002",
                                     prompt=prompts,
                                     n=5)

print(response)
```

We can further clean up our text by changing our print statement to the following:

Run the script again and Python will print five different responses to the prompt.

The Best Of Keyword Argument

```
response = openai.Completion.create(model="text-davinci-002",
                                    prompt=prompts,
                                    n=5,
                                    best_of=4)
```

You will generate an error essentially saying you requested the server to return more choices than it will generate. `n` needs to be less than or equal to `best_of`. We don't need to use `n` in order to use `best_of`. It will generate 4 completions but only print the "best" one.

TRY IT!

```
for i in (response["choices"]):
    print(i["text"].strip())
```

```
response = openai.Completion.create(model="text-davinci-002",
                                     prompt=prompts,
                                     n=3,
                                     best_of=3)
```

```
response = openai.Completion.create(model="text-davinci-002",
                                    prompt=prompts,
                                    best_of=3)
```

```
response = openai.Completion.create(model="text-davinci-002",
                                    prompt=prompts,
                                    n=3)
```

```
response = openai.Completion.create(model="text-davinci-002",
                                     prompt=prompts,
                                     n=2,
                                     best_of=3)
```

The correct answers are:

```
response = openai.Completion.create(model="text-davinci-002",
                                    prompt=prompts,
                                    n=3,
                                    best_of=3)
```

and:

```
response = openai.Completion.create(model="text-davinci-002",
                                    prompt=prompts,
                                    n=3)
```

The keyword argument `n` controls the number of responses GPT-3 returns. When `best_of = 3`, it will run three generations but only return the best one. These code samples are correct because `n = 3` in both of them.
