

Estimating Probabilities and Posterior Distributions Readings

For this lesson, read the following:

- [Section 2.1](#) : Estimating a probability from binomial data. This section looks at the simple binomial model, which aims to estimate a parameter that contains binary information (such as “yes”/“no” data).
- [Section 2.2](#) : Posterior as compromise between data and prior information. This section discusses how one can think of the posterior distribution, which is what we construct from the prior distribution and a new experiment.
- [Section 2.3](#) : Summarizing posterior inference. The posterior distribution contains all the information from which we are starting. In this reading, we discuss what it tells us.

You may download the PowerPoint and Notes used in this lesson's video lecture here:
