

Logistic Regression Problem

Asked 2 years, 5 months ago Modified 2 years, 5 months ago Viewed 119 times

▲
1 You are testing a new drug and have gathered binary data on whether the drug performed its desired effects. From the control trial, 102 people saw improvement with a placebo and 241 did not. With the drug, 67 people saw improvement and 82 did not. What is the odds ratio of these results?

▼
My solution is that $a = 102$, $c = 241$ for placebo and $b = 67$, $d = 82$ for drug, odds ratio should be $a * d / b * c = 102 * 82 / 67 * 241 = 8364 / 16147$, but it didn't seem to be right, can anyone tells what went wrong?
Much appreciated

I would have done $\frac{67/82}{102/241}$, i.e. putting the odds for the treatment on top. This give the reciprocal of your result – Henry Dec 5, 2021 at 15:36 ✎

1 ▲
Traditionally you would put the odds for the treatment group in the numerator when taking the ratio as noted by Henry. So an effective treatment has an OR > 1. But you also need to be careful if that's what you want. – Matcha Dec 5, 2021 at 17:13

Thanks @Henry, that works – jason Dec 6, 2021 at 0:13
