

Key Functions in the Next Video

In the next video you will learn a common approach to registering medical volumes. This reading introduces you to two functions you'll use in the video.

1. `[optimizer, metric] = imregconfig(modality)`

The algorithms and metrics used to register monomodal and multimodal volumes vary. Use the **`imregconfig`** function to specify either **`"monomodal"`** or **`"multimodal"`** as the modality. The **`optimizer`** and **`metric`** outputs are used in the **`imregister`** function.

See the [documentation](#)  for more information.

2. `movingReg = imregister(moving, fixed, transformType, optimizer, metric)`

The **`imregister`** function registers the **`moving`** image/volume to the **`fixed`** image/volume and returns the registered image/volume.

`transformType` are the types of transformations allowed during registration. This is often **`"rigid"`** or **`"similarity"`** for medical images.

`optimizer` and **`metric`** are the outputs from the **`imregconfig`** function and are used to set key parameters for the registration algorithm.

There are additional options you can input to the **`imregister`** function if needed. [See the documentation](#)  to learn more about these options.
