

Summary and Next Steps

Congratulations on finishing this course! You now have the knowledge and skills to start working with a variety of medical images. The meta-data associated with medical images is critical for properly viewing and interpreting them. Additionally, medical images are often volumes. Different machines and image sequences store the volume data differently. You can effectively work with medical volumes using the functions and Apps included in MATLAB.

This course is meant to complement our existing courses on image processing, computer vision, and deep learning. Below is a short description of what you'll learn and link to each specialization. We hope you'll continue learning with MathWorks and MATLAB!

[Image Processing for Engineering and Science](#)

Segmentation and analysis of segmented regions is one of the most common medical image analysis tasks. In this specialization you'll learned several approaches to segmentation and then analyze the segmented regions to determine properties like size and shape.

[Computer Vision for Engineering and Science](#)

If you need to register images, or count and track cells, this specialization is for you. Additionally, medical research studies often have limited data, and model interpretability is crucial. You'll learn traditional machine learning techniques to classify images. Traditional machine learning usually requires less data than deep learning approaches and makes predictions that are easier to interpret.

[Deep Learning for Computer Vision](#)

Deep learning models have shown great promise in classifying medical image like x-rays, detecting tumors and lesions, and identifying abnormalities that require further examination. In this specialization, you'll learn to train classification, object detection, and anomaly detection models.
