

What best describes a utility chain in LangChain?

In **LangChain**, a **utility chain** refers to a chain that performs **supportive or auxiliary tasks** rather than directly producing user-facing outputs. These chains typically help **transform, preprocess, or structure data** that will be used by other chains.

Best Description:

A utility chain is a chain designed to handle helper functions such as parsing outputs, formatting prompts, or transforming inputs/outputs within a LangChain application.

Examples of utility chains:

- **TransformChain**: Converts one data format to another (e.g., from a dict to a string).
- **LLMCheckerChain**: Verifies or filters LLM-generated output.
- **RouterChain**: Routes input to the appropriate sub-chain.
- **OutputParserChain**: Extracts structured data (like JSON) from raw LLM output.

Summary:

Utility chains **don't usually serve the end user directly**; they act as **middleware or tooling** to make the main chains more reliable, modular, and reusable.
