1. Suppose you want to build a collaborative filter to suggest new hiking trails for users. The problem is you don't have any good explicit user ratings for trails. What feature might be useful for creating an implicit measure of a user's rating for a trail instead? 1 / 1 point

- ☐ The length of the trail
- ☐ The distance of the trail to the user's home
- ☐ The number of times all users hiked that trail
- ☒ The number of times the user hiked that trail

Correct The decision to hike a trail can be reasonably interpreted as an implicit measure of user preference

2. What are some ways you can address the cold-start problem that can occur for new users of a collaborative filter recommendation system? There could be more than one answer. 1 / 1 point

- ☐ Give up and ask new users to make their own recommendations
- ☒ Rely on a content-based method instead for new users
- ☒ Correct Content-based systems require that we either base our recommendations solely on the properties of the items, by looking for similar items for example, or that we have representations of our users in the same embedding space of our items. For a trivial example, by asking users which genres they prefer, we could make content-based recommendations using representations of items with genres as features.
- ☐ Ask the new user's friends to recommend items they think would be relevant
- ☒ Ask the user for some basic preferences

Correct With only a few preferences, we could classify users into to different personas we've derived across our user-base and base our recommendations on the preferences of this entire group
