Quiz 5 - Summarizing Data
Graded Assignment • 10 min

Due Nov 16, 11:59 PM IST

Your grade: 100%

Your latest: **100%** • Your highest: **100%** • To pass you need at least 75%. We keep your highest score.

Next item →

1. What does **df.groupby(['genre'])** do? 1 / 1 point

- (●) It splits the data into different groups by 'genre'.
- ( ) It splits the data into different groups by default.
- ( ) It sorts the data based on 'genre'

Nice work

Correct. The method *groupby()* splits data into different groups based on variable(s) of your choice. Here we choose to split the data based on "genre".

2. Is the following statement True or False? 1 / 1 point

We can *pivot* a DataFrame without an index column.

- ( ) True
- (●) False

Nice work

Correct. In order to *pivot* a DataFrame, we need at least one *index* column to group by. The *index* is just like the variable(s) you group by in the *groupby* method.

3. Is the following statement True or False? 1 / 1 point

We can pass a *dict* object as an argument to *aggfunc*.

- (●) True
- ( ) False

Nice work

Correct. Besides passing a single numpy aggregation method, we can also pass a *dict* object containing different aggregate functions to perform on different values to aggfunc.

4. When creating a pivot table, what would happen if we don't specify any aggregation function? 1 / 1 point

- (●) By default, the pivot table calculates the average for every column in the result.
- ( ) By default, the pivot table calculates the summation for every column in the result.
- ( ) An error will occur.
- ( ) It will do nothing.

Nice work

This is correct. If we don't specify the aggfunc parameter in pivot_table function, it will by default display the mean values.

5. Which one is correct if we want to create a pivot table for DataFrame df indexing on column "author" and "title", and display the summation of the "res" column? 1 / 1 point

- ( ) import pandas as pd

  df_res = pd.pivot_table(df, index=["author", "title"], columns=["res"], aggfunc=[sum])
- ( ) import pandas as pd

  df_res = pd.pivot_table(df, index=["author", "title"], values=["res"], aggfunc=[pd.sum])
- (●) import pandas as pd

  import numpy as np

  df_res = pd.pivot_table(df, index=["author", "title"], values=["res"], aggfunc=[np.sum])
- ( ) import pandas as pd

  import numpy as np

  df_res = pd.pivot_table(df, index1=["author"], index2=["title"], values=["res"], aggfunc=[np.mean])

Nice work

To display summary statistics other than the mean, use the aggfunc parameter to specify the aggregation functions - here we use the sum method from the numpy package. Use the values parameter to specify the columns for aggfunc.
