

```
exercise1.py x
1 class Country:
2
3     def __init__(self, name, capital, population, continent):
4         self._name = name
5         self._capital = capital
6         self._population = population
7         self._continent = continent
8
9     @property
10    def name(self):
11        return self._name
12
13    @property
14    def capital(self):
15        return self._capital
16
17    @property
18    def population(self):
19        return self._population
20
21    @property
22    def continent(self):
23        return self._continent
24
25 my_country = Country('France', 'Paris', 67081000, 'Europe')
26 print(my_country.name)
27 print(my_country.capital)
28 print(my_country.population)
29 print(my_country.continent)
30
```

Encapsulation Exercise 1

Exercise 1

Define the `Country` class which has attributes for `name`, `capital`, `population`, and `continent`. Please use the Python convention for making these attributes private.

Expected Output

Initialize an object of the `Country` class as follows:

```
my_country = Country('France', 'Paris', 67081000, 'Europe')
```

Task	Output
Print the name attribute	France
Print the capital attribute	Paris
Print the population attribute	67081000
Print the continent attribute	Europe

Important

You do not need to create any getters or setters; just follow the Python convention for private attributes.

TRY IT

France
Paris
67081000
Europe

Submit your code when ready.

Here is one possible solution:

```
class Country:
    def __init__(self, name, capital, population, continent):
        self._name = name
        self._capital = capital
        self._population = population
        self._continent = continent
```

The Python convention for private attributes is the single leading underscore.

Check It!
