

Introduction to the Datasets

In course 1 of this specialization, you worked with images of fasteners and the American Sign Language (ASL) alphabet for classification tasks. In this course, you'll work with similar images, but this time for object detection.

ASL Images

Below are a few sample ASL images. All images in the dataset have a single person signing a letter of the alphabet. While the ASL alphabet has 26 letters, there are only 24 classes in this dataset because the letters J and Z include motion that is not easily captured with a single image. Having only one object per image makes this dataset easier to interpret and evaluate. Yet, the dataset is also complex because there are 24 classes and significant variation in how different people sign.

Notice how similar the letters M, N, and T are. Will a model be able to detect the hand and tell the difference?

Fastener Images

The fastener detection dataset offers a different challenge than the ASL dataset. There are only four classes in our detection dataset: Nails, Screws, Washers, and Nuts. However, most images have multiple objects. The objects are often close together or even touching. Will a model successfully locate objects that are touching and overlapping?

Here are some example images from the Fastener Dataset.
