# Exercise: Exceptions in Python

By the end of this exercise, you will be able to trap exceptions.

## Exercise

Your task in this exercise is to add code to trap exceptions and handle them in a more user-friendly way.

### IndexError

The below code has one problem. It is trying to locate an item from the list that does not exist. Running the code will throw the **IndexError**. Add exception handling to stop the error from being thrown and return a more user-friendly message such as "Item does not exist in the list".

```
1 # Starter code
2 items = [1,2,3,4,5]
3 item = items[6]
4 print(item)
5
```

Run

Reset

### ZeroDivisionError

In math there are rules about dividing by zero. The below code is trying to do just that and will throw a **ZeroDivisionError**. Add exception handling to return back 0 instead of allowing the error to be thrown.

```
1 # Starter code
2 def divide_by(a, b):
3     return a / b
4
5
6 ans = divide_by(40, 0)
7 print(ans)
8
```

Run

Reset

### FileNotFoundError

The code below is looking for a file that does not exist. Add exception handling to catch this error and return the following "The file could not be found".

```
1 # Starter code
2 with open('file_does_not_exist.txt', 'r') as file:
3     print(file.read())
4
```

Run

Reset

Completed
