Listen

A feedback loop in machine learning is a process that uses the output of an AI system to improve its models over time. It's also known as closed-loop learning.

Here's how a feedback loop works:

Compare output to final decision

The AI's predictions or recommendations are compared to the final decision, such as whether to perform a task.

Identify errors

The system identifies errors in the output and feeds them back into the model as input.

Learn from mistakes

The model learns from its mistakes and avoids making the same errors in the future.

Feedback loops can help machine learning models become more accurate over time. They can also allow for experimentation with different algorithms, training approaches, and data augmentation.

However, feedback loops can also have some potential drawbacks:

Reinforcing biases

If not carefully supervised, feedback loops can reinforce biases and lead to unfair or discriminatory results.

Double-edged sword

In some cases, feedback loops can be a double-edged sword. For example, in a crisis, an automated car with a feedback loop might have to make an instant decision that could hurt passengers or others.

Generative AI is experimental.
