6.6 Support Vector Machine Self-Check Quiz

1. Given a feature vector f of n dimensions, we want to find the decision boundary i.e. weight vector w and bias b such that $w^T f + b = 0$ that separates the faces from non-faces. How many parameters are we trying to find here? **1 / 1 point**

- 2
- n
- n + 1
- None of the above

Correct
The weight vector will also be n-dimensional, hence n weight parameters and an additional bias parameter.

2. How does the Support Vector Machine improve over the linear decision boundary method? **1 / 1 point**

- It makes computation faster
- It finds the most optimal decision boundary with maximum gap between data-points
- It uses less number of parameters
- None of the above

Correct
Refer to lecture video.

3. What is the minimum number of support vectors we need when we try to compute the decision boundary for a Face Detection problem? **1 / 1 point**

- 0
- 1
- 2
- 3

Correct
We must need at least one support vector from each +1 and -1 labeled data to be able efficiently compute the optimal decision boundary.
