

Lab - Pixel Art

Pixel Art Package

Pixel art is any piece of art built with the deliberate placement of pixels to create a larger image. The image below is an example of simple pixel art.

We are going to create `pixel_art`, a Python package that allows users to create pixel art and then print it to the terminal. The finished package will include the following items:

- `examples.py` - module that has several pre-made examples the user can display
- `pixels.py` - module that is the interface for building pixel art
- `__init__.py` - initialization file for the package
- `setup.py` - metadata for the package including dependencies
- `pixel_art` wheel - built distribution we will install to test the package
- Post to GitHub - keep a copy of the package in your own GitHub repository

Initializing the Package

Let's start by initializing the two modules for the `pixel_art` package. Copy this code into the `__init__.py` file.

```
import pixel_art.examples, pixel_art.pixels
```

Users can simply import `pixel_art` and both modules will be ready to go.

Lab Question

Select the line of code that would create the `requirements.txt` file.

☐

```
python3 -m pip require > requirements.txt
```

☐

```
python3 -m pip freeze
```

☒

```
python3 -m pip freeze > requirements.txt
```

☐

```
python3 -m pip dependencies > requirements.txt
```

The correct answer is:

```
python3 -m pip freeze > requirements.txt
```

The `freeze` command is used to generate the list of dependencies. However, the user needs to redirect that output to the correct file. This is what `> requirements.txt` does.

Check It!
