What are LLMs?

This [reading](#)  from Amazon explains what large language models are, why they are important, how they work, their applications, training methods, and future outlook. AWS offers services like Amazon Bedrock and SageMaker JumpStart to help developers build applications with LLMs.

Key Points

- LLMs are large deep learning models that understand relationships between words and phrases to generate natural language.
- LLMs power generative AI systems and have many applications like writing, knowledge base answering, classification, etc.
- Models like GPT-3, Claude, Jurassic have over 100 billion parameters trained on massive datasets.
- LLMs keep improving in accuracy and capabilities with advances in audiovisual training and workplace transformation potential.

Reflection Questions

- How do you think LLMs will impact content creation jobs in the next 5-10 years?
- What concerns do you have regarding bias, misinformation, and mistakes with LLMs?
- Would you feel comfortable using an LLM chatbot for complex customer service issues?
- How can models dynamically improve without requiring full retraining?
- Do you think LLMs should disclose when responses are auto-generated? Why?

Challenge Exercises

- Fine-tune a small LLM on a custom dataset with 100 training examples using Amazon SageMaker.
- Build a simple web app with an LLM API to answer frequently asked questions.
- Compare performance metrics of 2 language models on a classification task.
- Research capabilities outside of text that LLMs could potentially learn.
- Evaluate an LLM chat conversation for accuracy and coherence over 10 dialogue turns.
