1. When you're developing an AI application that needs to verify its responses against real-world data, why should you use a search-based grounding tool rather than relying on the model's internal knowledge? Select the best answer. 1 / 1 point

- The grounding tool increases the processing speed of the application by allowing the model to skip the reasoning phase.
- The grounding tool allows the model to synthesize its existing knowledge with real-time web results and cite specific, concrete sources.
- The grounding tool converts the response into a structured JSON schema without requiring a second model call.
- The grounding tool enables the model to bypass the API key and directly access public web indices.

Nice work

Correct! Grounding ensures that the AI's answers are based on fresh, external information. This reduces AI hallucinations and provides the user with verifiable sources for the information provided.

2. In a technical script where you've declared a function for an AI to use, why is it important to set additional properties to false within the parameter schema? Select the best answer. 1 / 1 point

- It increases the runtime of the script to allow the model more time to find the best options to respond to.
- It allows the model to suggest new properties that are not currently in the allowed list.
- It requires the model to ignore the user's input and only generate random values.
- It ensures the model only sends the specific keys defined in the schema and prevents it from including extra, unexpected data.

Nice work

Correct! By strictly defining the schema and prohibiting additional properties, you ensure that the model provides exactly what your function expects, reducing the risk of errors in your application logic.

3. A developer you are working with is trying to better understand the project the two of you are developing. He asks, "When we're developing intelligent systems, what differentiates a dynamic AI from a static AI?" Which of the following statements below would you answer with? Select the best answer. 1 / 1 point

- The difference is the ability to take in and react to real-time data from external sources, such as live traffic or the current inventory.
- The difference is determined by the total number of words the model is trained on before its release.
- The difference is the speed at which the hardware's CPU can calculate fixed values, such as road distances.
- The difference is the model's capacity to generate creative content, like stories or poetry, without human intervention.

Nice work

Correct! Similar to a live navigation app, a dynamic AI interacts with a changing environment. It doesn't just rely on fixed, pre-loaded knowledge; it can reach out to get the most current information available.

4. In the content retrieval and evaluation application you are currently working on, you find that you need to move from a standard Large Language Model (LLM) implementation to a dynamic AI agent. What is the most significant shift this change will make to the model's capability? Select the best answer. 1 / 1 point

- The model will start to ignore the user's initial persona instructions to prioritize speed and reduce total token costs in an effort to obtain and update new information.
- The model will be retrained on more recent data to make sure its internal knowledge remains current without external help.
- The model will use function calling to request help from external code to perform tasks or access real-time data.
- The model will increase its total word count and vocabulary to write more creatively, including things like sonnets and literature.

Nice work

Correct! This is the key that turns a static model into a dynamic agent. By speaking to your code via function calling, the model can overcome its isolation and interact with the outside world.

5. Why might a systems architect choose a standard text-generation prompt over a more complex agentic workflow for a specific application task? Select the best answer. 1 / 1 point

- To increase the reliability of the system by adding additional moving parts and more external APIs
- To allow the assistant to access a proprietary database lookup tool without writing any Python code
- To make sure the model can bypass human-in-the-loop requirements for sensitive financial transactions
- To reduce the time it takes for the system to respond and to minimize the total cost of tokens used

Nice work

Correct! Agentic workflows involve multiple "thinking" steps and back-and-forth communication with tools, which increases latency and token consumption. For simple tasks, a standard prompt is more efficient.
