Instructions

Review Learning Objectives

1. In linear regression, when using one-hot encoding for categorical variables, what does one-hot encoding entail? 1 / 1 point

COOCH

☐ Normalizing all numerical variables in the dataset. Ready to review what you've learned before starting the assignment? I'm here to help.

☒ Transforming each categorical value into a new column and assigning a binary value of 1 or 0. [Help me practice](#) [Let's chat](#)

☐ Assigning a unique numerical identifier to each category.

☐ Grouping all categories into a single column.

2. In the context of ordinal encoding used in linear regression, what is the main purpose of this technique? 1 / 1 point

Your grade

☐ To reduce the computational complexity of the model.

☐ To create binary columns for each category of a variable.

☒ To transform non-numeric variables into numeric ones while preserving the order of the categories.

☐ To increase the dimensionality of the dataset for better model performance.

100%

keep your highest score.

3. What is a potential drawback of using one-hot encoding in linear regression models? 1 / 1 point

☐ It increases the interpretability of the model by assigning unique weights to each category.

☐ It automatically handles missing data in categorical variables.

☒ It can introduce a high level of multicollinearity in the model.

☐ It can simplify the model too much, leading to underfitting.
