

Analysis of results

A second group of participants was asked to complete the same task. The second group, however, received an additional 2 hours of training beforehand. The question is whether the training is useful. Your task is to evaluate if the second group outperformed the first group. To do this, you will:

- Calculate the mean and standard deviation of the performances according to years of experience (1-5) for both group 1 (using 'group_1_clean.csv') and group 2 (using 'group_2.csv'). (Both in reading materials.)
- Store the calculated means and standard deviations in MATLAB matrices named 'means', and 'std_devs', respectively. Each matrix should have 5 rows (one for each experience level) and 2 columns (one for each group).

```
1 T1 = readtable("group_1_clean.csv");
2 T2 = readtable("group_2.csv");
3
4 %%% update the entries of the means and std_devs variables
5 for i=1:1:5 % i is the experience level
6     % Your code here:
7     % means(i,1) should be the average score of T1 with experience i.
8     means(i, 1) = mean(T1.Score(T1.Experience==i));
9     % std_devs(i,1) should be the standard deviation of the score of T1 with experience i.
10    std_devs(i, 1) = std(T1.Score(T1.Experience==i));
11
12    % means(i,2) and std_devs(i,2) are similar but for group 2.
13    means(i, 2) = mean(T2.Score(T2.Experience==i));
14    std_devs(i, 2) = std(T2.Score(T2.Experience==i));
15
16 end
```
