Main File

Before we start, we are going to create a main file with some functions. This way we can use the functions across different files. This way we have access to all our libraries, API keys and image generation file.

```
import os
import openai
from PIL import Image, ImageOps, ImageChops
from io import BytesIO
import requests

# Set environment variables
openai.api_key = os.getenv('OPENAI_KEY')

# Generate the base image
def generate_base_image(prompt):
    response = openai.Image.create(
        prompt=prompt,
        n=1,
        size="512x512"
    )
    return response['data'][0]['url']

def download_image(image_url, x):
    response = requests.get(image_url)
    img_data = response.content
    img = Image.open(BytesIO(img_data))
    with open(x+'.jpg', 'wb') as handler:
        handler.write(img_data)
    return img
```

TRY IT

Command was successfully executed.

This script essentially provides the functionality to generate an image based on a text prompt using the OpenAI API and then download and save that image to the local file system.

Now in all files we can just `import main` and we will have access to our library and functions.

Main purpose

Which of the following statements is true regarding the use of import `main` in other Python files?

- ☐ It allows the other Python files to use the OpenAI API
- ☒ It gives the other Python files access to the functions defined in the `main` file
- ☐ It sets the OpenAI API key for the other Python files
- ☐ It runs the main file's script in the other Python files

Check It!
